On the Second Moment of the Remainder Term Appearing in the Intermediate Order Statistic Representation

by

Vernon Watts

ABSTRACT

Under certain conditions a sample intermediate order statistic from a sequence of independent and identically distributed random variables has an almost sure representation involving the empirical distribution and a remainder term of small order. In this paper an asymptotic approximation of the second moment of the remainder term is obtained. It is assumed that the marginal distribution function of the independent and identically distributed sequence has a finite left endpoint.
1. **Introduction.** Suppose that \( \{X_i\}_{n \geq 1} \) are independent and identically distributed random variables on \((\Omega, F, P)\) with marginal distribution function (d.f.) \( F(x) = P(X_1 \leq x) \). Let \( \{k_n\}_{n \geq 1} \) be integers such that \( 1 \leq k_n \leq n \) for each \( n \) and \( k_n \to \infty \) but \( k_n/n \to 0 \) as \( n \to \infty \), and denote by \( x_{k_n}^{(n)} \) the \( k_n \)th smallest of \( X_1, \ldots, X_n \). Then \( \{x_{k_n}^{(n)}\}_{n \geq 1} \) is called a sequence of intermediate order statistics.

Define the left endpoint \( x'_0 \) of \( F \) by \( x'_0 = \inf \{x: F(x) > 0\} \), which we assume to be finite. Let \( F_n(x, \omega) = n^{-1} \sum_{i=1}^{n} I(X_i \leq x) \) be the empirical d.f. of the sample \( X_1, \ldots, X_n \). Then under certain conditions on \( F \), \( x_{k_n}^{(n)} \) has the representation

\[
(1.1) \quad x_{k_n}^{(n)}(\omega) = x_n' + \frac{k_n/n - F_n(x_n', \omega)}{F'(x_n')} + R_n'(\omega),
\]

where \( x_n' \) satisfies \( F(x_n') = k_n/n \) and where \( R_n'(\omega) = O(n^{-1}k_n^{1/4}\log^{3/4} n) \) as \( n \to \infty \) with probability one. (See Watts (1977).) In this paper we develop an asymptotic approximation to the second moment of the remainder term \( R_n' \), retaining the same conditions used to establish (1.1) and imposing some additional restrictions. Our procedure follows that employed by Duttweiler (1973) to approximate the second moment of the remainder term appearing in the Bahadur (1966) representation of sample \( \lambda \)-quantiles.

Since the expected value of the \( k \)th smallest order statistic of a sample of \( n \) variables uniformly distributed on the unit interval \( (0, 1) \) is \( k/(n + 1) \) rather than \( k/n \), it turns out that a substantial simplification in the procedure is effected by dealing with a representation for \( x_{k_n}^{(n)} \) which is slightly different from (1.1). We consider instead

\[
(1.2) \quad x_{k_n}^{(n)}(\omega) = x_n + \frac{k_n/(n + 1) - F_n(x_n, \omega)}{F'(x_n')} + R_n(\omega),
\]
where \( x_n \) is defined by \( F(x_n) = k_n / (n + 1) \). Then the methods used to prove (1.1) also show that \( R_n^2(n) = O(n^{-1} k_n^{1/4} \log^{3/4} n) \) with probability one.

2. **Derivation of the approximation.** The following preliminary result, which we state as a lemma, provides an exact expression for the second moment of \( R_n \) when \( F \) is the uniform \((0, 1)\) distribution. The details of proof are given by Duttweiler (1973).

**Lemma.** Let \( U_{k}^{(n)} \) be the \( k \)th smallest order statistic for the set \( U_1, \ldots, U_n \) of \( n \) independent random variables uniformly distributed on \((0, 1)\). Define

\[
(2.1) \quad \hat{U}_k^{(n)} = k / (n + 1) + \left(\frac{\sum_{i=1}^{n} I(U_i \geq k / (n + 1))}{n} - n(1 - k / (n + 1))\right)/n
\]

and let \( R = U_k^{(n)} - \hat{U}_k^{(n)} \). Then

\[
E(R^2) = \frac{2k}{n(n + 1)} \{ I_{k/(n+1)}(k, n + 1 - k) - I_{k/(n+1)}(k + 1, n + 1 - k) \} - \frac{2k(1 - k / (n + 1))}{n(n + 1)(n + 2)},
\]

where \( I_x(a, b) \) is the incomplete beta function, defined by

\[
I_x(a, b) = \frac{(a + b - 1)!}{(a - 1)!(b - 1)!} \int_0^x y^{a-1} (1 - y)^{b-1} dy.
\]

Now consider a general d.f. \( F \) for which \( x_0 > -\infty \). Suppose that \( F(x_0) = 0 \) and in an interval \((x_0, x_0 + \delta)\) \( F \) is twice differentiable with \( F'' \) bounded, and such that \( \lim_{x \to x_0} F'(x) \) exists and is positive. These assumptions insure that \( x_n \) is uniquely determined for large \( n \). If \( k_n / \log n \to \infty \) as \( n \to \infty \), then (1.2) holds with the indicated order of \( R_n^2 \). For the following result we make the additional restriction that the \( \{x_n\} \) have a finite second moment, that is, that \( \int x^2 \, dF(x) < \infty \), as well as a slightly stronger requirement on \( \{k_n\} \).
Theorem. Suppose the \( \{X_n\} \) have marginal d.f. \( F \) satisfying the above conditions
and that \( k/n^\theta \to \infty \) for some \( \theta > 0 \). Then for \( R_n \) defined by (1.2),
\[
E(R_n^2) \sim (2/\pi)^{1/2} k_n^{1/2} / (nF'(x_n))^2,
\]
as \( n \to \infty \).

Proof. Let \( U_1, \ldots, U_n \) be independent uniform \((0, 1)\) variables with \( k_n \)th
smallest order statistic \( U_{k_n}^{(n)} \). Define the quantile function \( Q(\cdot) \) by \( Q(u) = \text{sup}\{x: F(x) \leq u\} \). Then each \( Q(U_i) \) has d.f. \( F \), and
\[
R_n \sim Q(U_{k_n}^{(n)}) - x_n - \frac{n k_n}{n + 1} \sum_{i=1}^{n} I(Q(U_i) \leq x_n) \frac{n F'(x_n)}{n F'(x_n)},
\]
where \( \sim \) indicates having identical distributions.

We may suppose that \( F'(x) \) is positive in the interval \( A = (x_0, x_0 + \delta) \). Let
\( B = \{u: u = F(x), x \in A\} \). Then \( Q \) restricted to \( B \) is the inverse of \( F \) restricted
to \( A \). Let \( p_n = k_n / (n + 1) \). There is an integer \( N_1 \) such that \( p_n \in B \) if \( n \geq N_1 \),
and we have that
\[
Q(p_n) = x_n,
\]
\[
Q'(p_n) \text{ exists and equals } (F'(x_n))^{-1},
\]
and
\[
Q(u) \leq x_n \text{ if and only if } u \leq p_n.
\]
Also, \( Q'' \) exists and is bounded in \( B \), and a straightforward derivation shows that
\[
\int_0^1 Q(u)^2 \, du = \text{EX}^2 < \infty.
\]

For \( n \geq 1 \) and \( u \in [0, 1] \) define
\[
H_n(u) = Q(u) - Q(p_n) - Q'(p_n)(u - p_n).
\]
Then by (2.2)-(2.4) for \( n \geq N_1 \) we have that

\[
R_n \xrightarrow{\mathcal{D}} Q(p_n) + Q'(p_n)(U_{k_n}^{(n)} - p_n) + H_n(U_{k_n}^{(n)}) - x_n - \frac{\sum_{i=1}^{n} I(U_i \leq p_n)}{n F'(x_n)}
\]

(2.5)

\[
\xrightarrow{\mathcal{D}} H_n(U_{k_n}^{(n)}) + (F'(x_n))^{-1}(U_{k_n}^{(n)} - \hat{U}_{k_n}^{(n)}),
\]

where \( \hat{U}_{k_n}^{(n)} \) is given by (2.1). Now by Lemma 1,

\[
E(U_{k_n}^{(n)} - \hat{U}_{k_n}^{(n)})^2 = \frac{2k_n}{n(n+1)} \left\{ I_{p_n}(k_n, n + 1 - k_n) - I_{p_n}(k_n + 1, n + 1 - k_n) \right\} + O(k_n/n^3).
\]

Applying the relation

\[
I_x(a, b) - I_x(a + 1, b) = (a + b - 1)! \left( \frac{a}{a! (b - 1)!} \right) x^a (1 - x)^b
\]

for positive integers \( a \) and \( b \) (see Abramowitz and Stegun (1964, Equation 26.5.16)) and Stirling's formula

\[
n! = e^{-n} n^{n+1/2} (2\pi)^{1/2} (1 + O(n^{-1})),
\]

we obtain

(2.6)

\[
E(U_{k_n}^{(n)} - \hat{U}_{k_n}^{(n)})^2 = (2/\pi)^{1/2} (k_n^{1/2}/n^2) (1 + o(1)).
\]

Therefore to complete the proof of the theorem it is sufficient from (2.5) and (2.6) and by the Schwarz inequality to show that

(2.7)

\[
E(R_n^2(U_{k_n}^{(n)})) = o(k_n^{1/2}/n^2).
\]

Choose \( \alpha, 0 < \alpha < 1/8 \), and let \( \varepsilon_n = k_n^{\alpha}/n^{1/2} \) and \( I_n = (\max\{0, p_n - \varepsilon_n\}, p_n + \varepsilon_n) \).

We may assume that \( I_n \subset B \). Denoting the probability density of \( U_{k_n}^{(n)} \) by \( g_n \), we have
\[ E \hat{H}^2_n(u^{(n)}) = \left( \int_{u \in I_n} + \int_{u \notin I_n} \right) H^2_n(u) g_n(u) \, du. \]

Let \( H_{n,\text{max}} = \sup_{u \in I_n} |H_n(u)| \) and \( g_{n,\text{max}} = \sup_{u \notin I_n} g_n(u) \). Then

\[ E \hat{H}^2_n(u^{(n)}) \leq H_{n,\text{max}}^2 + g_{n,\text{max}} \int_0^1 H^2_n(u) \, du. \]

Also, it follows from the inequality \((a + b + c)^{2/3} \leq a^2 + b^2 + c^2\) that

\[ \frac{1}{3} \int_0^1 H^2_n(u) \, du \leq E X_1^2 + Q^2(p_n) + (Q'(p_n))^2. \]

Since \( E X_1^2 < \infty \), by (2.2) and (2.3), and since \( F'(x_n) \) tends to a non-zero limit, 
there is a constant \( C_1 < \infty \) such that for \( n \geq N_1 \), 

\[ \int_0^1 H^2_n(u) \, du \leq C_1. \]

Hence for \( n \geq N_1 \),

\[ (2.8) \quad E \hat{H}^2_n(u^{(n)}) \leq H_{n,\text{max}}^2 + C_1 g_{n,\text{max}}. \]

Then letting \( C_2 = \sup_{\mathbb{E} \in \mathbb{B}} \{ |Q''(u)| \} < \infty \), we have by Taylor's expansion that 

\[ |H_n(u)| \leq C_2(u - p_n)^2/2 \text{ for } u \in I_n, \text{ and therefore} \]

\[ (2.9) \quad H_{n,\text{max}}^2 \leq C_2 \varepsilon_n^4/4 \text{ if } n \geq N_1. \]

Next, we observe that the density

\[ g_n(u) = \frac{n!}{(k_n - 1)! (n - k_n)!} u^{k_n-1} (1 - u)^{n-k_n}, \quad 0 < u < 1, \]

has mode \( m_n = (k_n - 1)/(n - 1) \) and decreases monotonically on both sides. Since
\[ |m_n - p_n| = o(\epsilon_n), \quad m_n \in I_n \text{ for } n \geq N_2 \geq N_1. \] Let \( \kappa \geq 1. \) We have

\[
E(U_k^{(n)} - p_n)^{2\kappa} \geq \int_0^{1 - p_n} (u - p_n)^{2\kappa} g_n(u) \, du
\]

\[
\geq g_n(p_n + \epsilon_n)(2\kappa + 1)^{-1}(\epsilon_n)^{2\kappa+1} - (m_n - p_n)^{2\kappa+1},
\]

and since \( n \epsilon_n \to \infty \) whereas \( m_n - p_n = o(n^{-1}) \), there exists \( C_3 < \infty \), depending on \( \kappa \), such that

\[
g_n(p_n + \epsilon_n) \leq C_3 \epsilon_n^{-(2\kappa+1)} E(U_k^{(n)} - p_n)^{2\kappa}
\]

for \( n \geq N_3 \geq N_2 \). In a similar manner there exists \( C_4 < \infty \) such that

\[
g_n(p_n - \epsilon_n) \leq C_4 \epsilon_n^{-(2\kappa+1)} E(U_k^{(n)} - p_n)^{2\kappa}
\]

for \( n \geq N_3 \). Then letting \( C_5 = \max(C_3, C_4) \) gives

\[
g_{n, \max} \leq C_5 \epsilon_n^{-(2\kappa+1)} E(U_k^{(n)} - p_n)^{2\kappa}.
\]

Since (see Blom (1953, p. 42)) there is a constant \( C_6 < \infty \) independent of \( n, k_n \), and \( \kappa \) such that

\[ E(U_k^{(n)} - p_n)^{2\kappa} \leq C_6 n^{-\kappa}, \]

it follows that

\[ g_{n, \max} \leq C_6 C_5 n^{-\kappa} \epsilon_n^{-(2\kappa+1)} \]

for \( n \geq N_3 \). Then (2.8), (2.9), and (2.10) lead to

\[ E H_n^2(U_k^{(n)}) \leq C_2^2 \epsilon_n^4/4 + C_1 C_6 C_5 n^{-\kappa} \epsilon_n^{-(2\kappa+1)} \]

for \( n \geq N_3 \). Finally we may suppose that \( k_n \geq n^\theta \) for some \( \theta > 0 \), so that

\[ n^{-\kappa} \epsilon_n^{-(2\kappa+1)} \leq n^{1/2 - \theta\alpha(2\kappa+1)} \]

and by choosing \( \kappa \) sufficiently large we obtain (2.7). \( \square \)
